Abstract

Pre- and perinatal loss and grief tend to be referred to as complicated grief denoting the experience of ongoing trauma. It is considered a burden for the affected parents, their families and the helping professionals alike. Yet this phenomenon remains an underrepresented field in analytical studies. Our aim is to systematically review the literature that deals with personal grief caused by pre- and perinatal loss - as experienced by healthcare staff. We shall present a comprehensive view of relevant international and national attitudes including existing grief management options. The above-mentioned complex issue deserves greater attention, which should result in the establishment of dynamic, up-to-date support programmes on all professional levels.

Keywords: perinatal loss, complicated grief, coping strategies, professional difficulties

What is known about the topic?

The personal and professional challenges experienced by healthcare personnel when facing perinatal loss have only been acknowledged recently.

This newly arisen interest has generated relatively few scientific publications, the majority of which cover study reports of individual researches, whereas a small number of them ventures to provide a systematic critical reading of theoretical and research-based studies of the last two decades approximately.

What does this article contribute to existing knowledge?

It is a freshly updated review with a time span until December 2018.

It sets out to systematically consider existent publications, focusing on the quality of individual studies and theoretical discussions, highlighting the ever-increasing global need to support caregivers in perinatal departments.

Propositions for practice and protocols

This article underlines the importance of support and the creation formation in the field of perinatal care, showing that the provision of more profound information and skills development training may significantly help healthcare professionals to face perinatal loss. On a more systematic level, the formation of national protocols and national guidelines is accentuated.

1. Introduction

The analysis of the loss and grief experiences of healthcare professionals - including the study of coping strategies and competencies to process these significant work-related events - is a relatively new field of research at international and domestic (Hungarian) levels. (1, 2) Although literature reviews and research studies on loss and grief have been produced extensively, assessments of the effect of loss and mourning on medical staff have seemingly been ignored so far, even though traumatic events influence their professional and personal attitudes as well. This problem is all the more significant if one considers the fact that grief and trauma caused by perinatal loss - if not assisted and confronted properly - may easily develop into a phenomenon of complicated
grief. As such, it represents an increased burden for the affected families, their immediate environment and also for the professional staff helping them. This may probably be one of the greatest losses a person can suffer. The pain caused by death and mourning multiplies when an eagerly anticipated new life comes to an abrupt end, suddenly and unexpectedly. Moreover, even sepulchral problems may arise at the loss of infants who die in the womb or are stillborn.

The objective of the present study is to systematically review the literature regarding healthcare professionals affected by pre- and perinatal loss. We seek to obtain an overall view of the internationally acknowledged professional attitudes and solutions related to the impacts of pre- and perinatal infant death.

2. Methodology

2.1 Selection Criteria Regarding the Articles Consulted in the Analysis

This literary overview mainly includes studies which deal with the difficulties and/or attitudes related to grief and loss as experienced by those working in pre- and perinatal healthcare. Literary synopses and research studies are also in focus, offering tangible solutions to tackle the identified problems. Dissertations and doctoral theses, however, are excluded from the resources under scrutiny.

The majority of subjects in the studies are nurses (women only, underscoring an occupation that is vastly female-dominated) and medical doctors. Fewer studies deal with the doctors’ attitudes and their experiences of loss. (3)

2.2 Applied Research Methods and Databases

The databases that we used include PubMed, Ovid MEDLINE, Ovid PsycINFO, Proquest, Scopus, CINHAL and the Hungarian Medical Bibliography (Magyar Orvosi Bibliográfia). Initially, the terms ‘perinatal loss and grief’ were the keywords that we applied to perform a search, then we narrowed it down by adding the words ‘nurse’ and ‘doctor’. When searching the Hungarian database, we also applied the keyword ‘perinatal loss’ (perinatális veszteség). As our aim was to collect the most recent publications, the publication period was set between 2005 and 2018, allowing formerly published significant articles focusing on the topic of our interest to be included as well.

3. Data Collection and Analysis

The database search results are, as follows:

Table 1. Numbers of hits for keyword searches

<table>
<thead>
<tr>
<th>Database</th>
<th>No. of hits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ovid MEDLINE</td>
<td>611</td>
</tr>
<tr>
<td>Ovid PsycINFO</td>
<td>93</td>
</tr>
<tr>
<td>Proquest</td>
<td>1432</td>
</tr>
<tr>
<td>Scopus</td>
<td>167</td>
</tr>
<tr>
<td>CINHAL</td>
<td>78</td>
</tr>
<tr>
<td>PubMed</td>
<td>88</td>
</tr>
<tr>
<td>MOB</td>
<td>2</td>
</tr>
</tbody>
</table>

When examining the findings, we narrowed down the results focusing on healthcare professionals’ experiences of grief and loss, as follows:

Table 2. Number of hits of publications focusing on the grief and loss experiences of healthcare personnel

<table>
<thead>
<tr>
<th>Database</th>
<th>No. of hits</th>

<td>5</td>
</tr>
<tr>
<td>MOB</td>
<td>2</td>
</tr>
</tbody>
</table>
It is important to emphasise that there are significant overlaps among different databases, thus the search results are not 100% accurate. Eventually, we identified 29 scientific publications that met our preset search criteria. The collected articles were firstly divided into categories on the basis of the healthcare professionals they targeted. Both doctors and nurses (midwives) were in the focus of 11 studies. There were 11 published researches concentrating on nurses, whereas doctors represented the exclusive subjects of only 4 analyses. Other professionals also present in pre- and perinatal care (i.e. psychologists, perinatal specialists, general practitioners) were not included in any international studies.

The qualitative analysis of the publications was performed according to the following criteria and order: author, place and time of publication, country, type of study, applied method(s), number of participants, field of activity, main research topics and results. We summarised our findings in a table.

The secondary diagnostic criterion was the publication date. As mentioned before, we strived to focus on and select for our overview the scientific writings of the last decade or so.

In terms of the limits of the literary overview, several publications concerning our topic of interest are healthcare recommendations or protocol measures, which are not available directly in the searched databases but only via specific homepages dedicated to pre- and perinatal loss:

All in all, 29 studies were collected on the basis of our criteria. Pre-2005 publication dates were also considered if the works published then shared the focus of the present review. The categorisation of the articles - based on their nature - is, as follows: original publications: 23, out of these research reports: 20, theoretical analyses: 3; literary overviews: 6. According to the place of publication and the nationality of the authors, 11 publications come from the United States, 4 are British, 3 are Hungarian, 2 works per country belong to Italy, Ireland and Israel, while Australia, Brazil, Singapore and South-Africa have 1 material each.

The results of the research activity can be seen in Table 3 of the Appendix.

4. Discussion

A noteworthy tendency can be recognised in the publications, namely that growing attention is paid to healthcare professionals’ personal and occupational problems arising from chronic distress, emotive involvement, personal grief and the non-appropriate elaboration of their feelings of grief and loss. A correlation can be identified between the help provided to bereaved families and the effects of personal involvement, the existence or lack of supervision and of expected training facilities. Should the latter ones become available on a regular basis, the elaboration of grief and loss may be much easier. (1, 2, 3)

Regarding earlier relevant analyses, the novelty of this study lies in the recognition that the acute and chronic experiences of loss impact not only the physical health of healthcare staff but their psychosocial well-being as well. (4, 5) Medical and nursing staff must be able to acknowledge that all experiences of loss affect their physical and mental health. (3) ‘Cushioning’ the psyche is mentioned as a quasi instinctive coping strategy against the experiences of loss by Gerow et al. (6) They put special emphasis on the necessity of appropriate elaboration of grief and loss for an adequate level of continuous professional performance. Gold et al (3) argue that such objectives can only be achieved via death education and competency development. This strategy enabled the examination of the problem on one of the largest scales: out of 1,500 doctors, more than 800 filled in and returned the questionnaire.

The researches show that the source of distress caused by loss and grief is differently experienced by nurses and doctors. While both professions consider help provided to patients as their highest priority, in the case of doctors proper decision-making regarding therapeutic solutions is equally essential(5), while for nurses caregiving and establishing a good relationship with individuals are of key importance, too. (1)

Most of the interviewed doctors claimed that perinatal death and loss represented significant emotional burden for them, some of them even considered changing their profession because of the experienced difficulties. (5, 7, 8, 9) This tendency can be recognised among nurses as well, although their personal attitudes are fairly dissimilar, as demonstrated previously. (9, 10) The analysed samples, except for the study of Roger et al from 2008 (n=890) (10), are all rather short (n≤100), they mostly present results of researches conducted in a given institute (1, 6, 8, 10, 11), focusing on the attitudes and issues of their own staff.

Two publications regarding Hungarian approaches to the problem should also receive critical attention. As demonstrated by the summary table, two decades passed between the two relevant researches, and no similar
publication was issued in the meantime. (2, 12) The subjects in Török and Szeverényi’s studies are obstetricians (2), while the research of Zsák et al also focuses on neonatologists, paediatricians, obstetricians, nurses, childcare specialists and psychologists (12). According to the results published to date, no significant change can be observed between the two Hungarian healthcare subject groups regarding the topic of our interest. The subject groups are characterised by very similar communicative, psychological and interpersonal difficulties as well as by similar attitudes concerning pre- and perinatal losses.

Interestingly, the majority of the relevant publications consist of reports of individual studies (1, 3, 5, 8, 11, 12, 13, 14, 15, 16, 17 18 and 19), potentially highlighting the recent attention to the importance of the topic. It may also suggest increased awareness of the personal needs of healthcare professionals, expressed via local institutional practices. The burden of loss seems to be experienced in the same way regardless of people’s geographical locations. Personal attitudes are investigated by qualitative research methods including IPA (eg. 5, 17), conducted via semi-structured interviews. A theoretical approach to grief and loss experiences is supplied in the articles by Mander (19) and Hogan (20), while linguistic analysis is also implemented to enter the core of the problem (21). Review of the recently published academic material is accomplished in different sources (22, 23 and 24) from culturally diverse environments, Singaporean, Hungarian and American, respectively.

4.1 Proposals to Solve the Identified Problems

Healthcare workers must be made aware of the potential health risks of untreated acute and chronic loss experiences. Likewise, they should be provided with information on the significance of supervision, psychosocial support and bereavement therapies, professional as well as personal, highlighting the efficacy of this sort of bereavement support. Good personal relations with the patients and their families may be one of the ways of elaborating grief, while external help via psychotherapy, mental hygiene or spiritual methods can be considered a beneficial alternative. (1) Rogers et al (10) claim that providing continuous support (through external professionals) to PIC personnel after the death of each child is vital. Competencies and knowledge acquired from death education or thanatology appear to be other sources of adequate care, aiding the elaboration of subjective feelings. As per the findings of Gold et al and Gerow et al (3, 6), developing adequate coping strategies may contribute to the successful cultivation of relevant competencies.

For doctors, as it is revealed in the latter special focus on them, the opportunity to talk, either in a personal or professional ambiance (the latter one stands for 87% of the cases), is the mode to elaborate and ventilate their emotions. (3) On the other hand, they need individual coping strategies or competencies that if applied repetitively may help them move forward after each experience of loss. (25) The Brazilian publication emphasises the need for a protocol, and at the same time it underlines the importance of individual care and support. (11) The implementation of concrete supportive programmes is evaluated by Gallagher et al (26), Gardiner et al (27), Cartwright and Read (28), and McGrath (29).

4.2 Strengths and Limitations

The strength of this review lies in its ability to provide a comprehensive summary of the materials published in the last two decades dealing with the personal and professional attitudes of and difficulties experienced by healthcare operators in relation to perinatal loss and grief. The overview reveals an increasing need regarding the challenges that caregivers encounter, whether in private or in working conditions. The selection criteria may have been limited to a relatively great extent by only using the keywords ‘perinatal’ and ‘perinatal’; as some research findings allow to suppose, other terminologies or approaches could also have been used for articles with a similar focus.

5. Conclusion

The results of this survey clearly demonstrate the significance and complexity of the main subject matter, namely, that more attention must be paid to the aftermath of traumas. This could include the provision of dynamic, accessible and up-to-date supervisory programmes available on each formative level of professional education. Although the publications consulted so far focus on the attitude of already skilled and active personnel, they also support the fact that early integrative educational programmes can be exceptionally beneficial. One of the greatest advantages of such opportunities is that they simultaneously centre on loss, grief and mourning as well as on the development of individual coping strategies, communication skills and emotional competencies in psychological, social and spiritual ways alike. On a more systematic level, the formation of national protocols and national guidelines is accentuated in our findings. Similarly to the previous solutions, these arrangements may greatly ease the difficulties and challenges that healthcare operators face when encountering cases of perinatal loss in their practices.

Experiences with perinatal loss from the health professionals’ perspective

Pastor Montero SM, Romero Sánchez JM, Hueso Montoro C, Lillo Crespo M, Vacas Jaén AG, Rodríguez Tirado MB. Rev Lat Am Enfermagem. 2021 Brazil original interviews, qualitative study 19 professionals

The aim was to identify coping strategies in perinatal loss. The focus is on the applied healthcare procedures, the emotions of the healthcare staff, on the beliefs and concepts of grief and loss. Insufficient level of knowledge, lack of competencies and skills generate feelings of incapacity, powerlessness and frustration in professionals. Appropriate formative programmes and guidelines are required to resolve problems.

Good grief: staff responses to childbearing loss

Mander RN. Nurse Educ Today 2009 UK original case studies n/a

Emotional implications of staff in case of loss in perinatal circumstances are in the focus of the paper. While education is a way to help staff grief, it still remains a very sensitive situation in need of further attention. Document the experiences of intrapartum death (IPD), to identify opinions, education and suitable support strategies.

Healthcare professionals’ response to intrapartum death: a cross-sectional study

McNamara K et al. Arch Gynecol Obstet. 2017 Ireland original quantitative study n/a

Document the experiences of intrapartum death (IPD), to identify opinions, education and suitable support strategies.

How physicians cope with stillbirth or neonatal death: a national survey of obstetricians

Gold KJ, Kuznia AL, Hayward RA. J Obstetrics and Gynecology 2008 USA original a questionnaire, sent by post in 3 copies, with focus on experiences and attitudes regarding perinatal loss out of 1500, randomly selected American obstetricians 804 (54%) filled in and sent back the complete questionnaire

75% of the interviewed physicians consider perinatal loss as an emotional burden, approx. 10% have already thought of changing profession because of this. Main coping strategies are conversations with colleagues (87%), family or friends (56%). Thanatology courses are help to provide adequate support and to elaborate their own feelings.

Intrapartum fetal death and doctors: a qualitative exploration

McNamara K, Meaney S, O’Donoghue K. Acta Obstet Scand 2018 Ireland original qualitative study, IPA 10 physicians

In-depth qualitative exploration of the attitudes and responses obstetricians have following direct involvement with intrapartum fetal death. Obstetricians were profoundly and negatively affected by a personal involvement with an intrapartum death. Doctors directly involved in an intrapartum death are the second victims. Effective emotional support intervention is important.

La morte perinatale. Aspetti psicologici del lutto e strumenti d’intervento (Perinatal death. Psychological aspects of bereavement and clinical practice)

Ravaldi, Claudia. Rivista Sperimentale di Freniatria 2014 Italy original review summary

Negative feelings due to pre- and perinatal loss, frustration coming from not providing needed care and support, experiencing professional failure and attitude towards death are the most significant factors in healthcare professionals’ care-giving.

Exposure to perinatal death may add significant stress. Two studies on obstetrics nurses. Study 1: obstetrics nurses showed a higher level of psychiatric symptoms [posttraumatic stress disorder (PTSD), depressive, and psychosomatic symptoms]. Study 2: a higher level of psychiatric symptoms (PTSD, depressive, and psychosomatic symptoms) in the exposed group in comparison to the non-exposed group. The effect of exposure to perinatal death is severe and needs to be addressed by developing intervention and preparation.

Study of the impact of perinatal loss on health professionals’ language. A linguistic analysis was performed using the Linguistic Inquiry and Word Count software. Associations between language and burnout were studied. Words typical of a psychological shock reaction were used more by non-medical staff than by physicians. Clinical implications of the results are discussed.

Aiming to explore the impact of stillbirth and to research the lived experience of health care consultants in a tertiary university hospital in Ireland. Main findings: personal impact (effecting the provided care for patients) and weight of professional responsibility (professional burden and medicolegal concerns). Need for specialist training in bereavement care.

Methodological study about clinical and educational needs in paediatric palliative care. The analysis, focusing on the needs of parents and professional staff, too, serves as a basis to develop special methods, emotional and cognitive competencies, as well. Relationship is the defining factor, the frame that serves as a base of support for grieving parents. Follow-up support provides care and hope for the families experiencing loss. Professional staff need to find proper ways of self-support and care.

A systematic literary review of the academic writings published between 2005 and 2016 in order to provide an overview of the international research activities. The focus is on the help and
support healthcare professionals may have following exposure to perinatal child loss. Working with practitioners to develop training in perinatal loss and bereavement: Evaluating three workshops

Pat Cartwright, Sue Read
Nurse Education in Practice

2005 UK
original evaluation of a specialization programme
21 participants (nurses, obstetricians)

Implementation and evaluation of a formative course for healthcare staff in perinatal care. The formative model originally set up for the caregiver nurses was also adapted for the needs of the midwives.
