Abstract
The effect of TPA and biochemical properties of Yellow Tuna during frozen storage at different temperatures (-18°C, -25°C, -35°C, -45°C, -55°C, -65°C) were studied by measuring the textural characteristics (the hardness, Springiness) salt-solubility of myofibrillar proteins, Ca²⁺ATPase activities. The results indicated that the hardness, springiness, actomyosin salt-solubility, Ca²⁺ATPase activities decreased during the process of frozen storage. Meanwhile, the frozen stored temperature showed great effect on the freezing denaturation of protein (P < 0.05). For the same longer of the storage time, the lower frozen temperature, the less extent of freeze denaturation; Stored in -18°C for three months, the content of Salt soluble protein reduced to zero; Stored in -25°C for 120 days, the content of salt soluble protein also reduced to zero; But stored in -55°C and -65°C, the change is very little. Ca²⁺ATPase activities also reduced to zero after stored in -18°C and -25°C for three months. But stored in -55°C and -65°C, there is no obvious change. Moreover, there is a Positive relationship between the change of texture profile and the content of Salt soluble protein, the lower the storage temperature, the less of the change of texture profile. Therefore, when it is stored in -55°C, the quality of Yellow Tuna can be maintained to the maximum extent within six months.

Keywords: tuna, ultra-lowtemperature, texture profile analysis (TPA), biochemical properties

1. Introduction
Yellowfin tuna (Thunnus albacares) are pelagic fish ,usually living in tropical and temperature waters. Its main habitat is usually in the depth of 50~250 m, and the depth depends on the season and the different areas of sea level. Tuna meat is tender, tasty, high protein. Thus it has high nutritional value. However, the tuna meat preservation conditions are harsh. In the process of refrigeration, the good quality of tuna meat will lose. In order to make the tuna the same color and texture, tuna meat is frozen in the low temperature of -80°C. But meanwhile it consumes too much energy. The texture, salt-soluble protein content, Ca²⁺ATP activity, WHC values of yellowfin tuna back muscles were studied at different frozen storage temperatures and finding the best frozen temperature was -55°C, which can guarantee the quality and save more energy. In this study, it is provided some theoretical basis for controlling tuna meat quality and transport.

2. Materials and Methods
2.1 Materials
Tuna was donated by a local tuna factory (Yuanyang, Ningbo); Ca²⁺ATPase kit was bought by Reagent Company (Jiancheng, Nanjing); All other chemicals were analytical grade products.

2.2 Fish Sample and Storage Condition
Take four Yellowfin tunas of the same size and divide each of them into four parts, then divide the back muscles of the each part into the shape of trapezoid. Take 500 g of the back muscles of the tuna, and then pack it in sealing. Then frozen it for 6 months in different temperatures (-18°C, -25°C, -35°C, -45°C, -55°C). It was measured every 15d before test it was thawed at 4°C in order to eliminate the influence of low temperature.
2.3 Determination of Texture

Take the TMS-Pro material analyzer under the measuring mode of Texture Profile Analysis (TPA) the size of whose probe is P/20. The speed of the probe before the test when testing are both 1 mm/s. The ratio of the compression is 60%, trigger type is automatic 1N. The reciprocating motion is done by two times, test three times of each sample by the quality and structure analyzer. The sample is the muscles of the back of the tuna, of which the size is $3 \times 3 \times 3$ cm. the hardness, Springiness, Cohesiveness as the studied object.

2.4 The Extraction of the Actomyosin Salt-Solubility

Get 5 g fish, adding 10 times of the amount of Tris-HCl buffer (pH7.05), meanwhile homogenize three times at speed of 20000rpm, each time within 30s, then centrifuge 15min with 10000r/min under low temperature (4°C). After that discard the supernatant and precipitate with cold 0.1MKCl 50mM Tris-HCl (pH = 7.05) anddissolve in buffer solution. After fully homogenized at 4°C to extract salt-soluble protein 1h, centrifuge at 9000r/min under 10min, and supernatant is the experimental actomyosin salt-solubility protein solution. actomyosin salt-solubility quantification: Coomassie brilliant blue method.

2.5 Ca$^{2+}$ ATPase Values

Using Nanjing Jiancheng ATP kit

Operating procedures:
1) Enzymatic reactions: the instructions 100l added to the sample and reagent mixing, 37°C accurate for 10 minutes;
2) Plumed R7,3500 rev / min, centrifuged for 10 minutes and got the supernatant
3) Phosphorus compounds was added into the supernatantat room temperature for 2 minutes and plumed terminator
4) At 636 nm wavelength, 1 cm light path, colorimetric

2.6 Statistical Analysis

Data are expressed as mean values (n =3) accompanied by the standard errors of means. Data from the different composition and quality parameters were subjected to one-way ANOVA ($p<0.05$) by employing an SPSS software (version 17.0). Comparison of means after the ANOVA test was performed using the Duncan’s multiple range test ($p<0.05$).

3. Results and Discussion

3.1 Texture Profile Analysis

![Figure 1. Effect of different storage temperatures on the Hardness of Tuna](image-url)
Texture and appearance of food, flavor, nutrition together constitute the four quality factors of the food (Kristiansen et al., 2007). Hardness showed the tactile sense of human body soft or hard, the power can make food to a certain deformation. we can draw the conclusion from the figure, in the frozen process, the longer the frozen storage time, the smaller the hardness gradually became, but at different temperatures, the hardness changes ($p < 0.05$) significantly. When frozen at -18°C, the hardness of tuna changed maximum and frozen for six months, the hardness decreased from the beginning of 22.7 N to 8.98 N and dropped 61%; -25°C frozen, the hardness dropped 46.5%; -35°C frozen, the hardness dropped 26.9%; -45°C the hardness dropped 23.1%; -55°C the hardness dropped 17.1%; -65°C the hardness dropped 16.5%. The change of hardness related to the decrease of salt-soluble protein content and enzyme activity. On the one hand, during the frozen because ATP activity decreased fast, leading to serious action protein denaturation. On the other hand, due to the process of frozen, free water in tuna meat frozen into ice crystals, formed mechanical damage to the muscle cells, changed the protein three-dimensional structure, resulted in the decrease of muscle hardness (Katsunori et al., 2009; CHOW et al., 1985).

![Figure 2. Effect of different storage temperatures on the Springiness of Tuna](image)

Springiness reflected the recovery degree of deformation after eliminating force in external force. From the chart above, in the frozen process, when frozen at -18°C, the Springiness change of tuna was maximum and frozen for six months, the Springiness decreased 57.8%; -25°C the Springiness decreased 46.5%; -35°C frozen, the Springiness decreased 26.9%; -45°C the Springiness decreased 23.1%; -55°C the Springiness decreased 17.1%; -65°C the Springiness decreased 16.8%. The change of Springiness related to the degree of protein denaturation (WOOJ et al., 2007; Sato et al., 1986; Luis, 1999).

3.2 Actomyosin Salt-Solubility Analysis

We can draw the conclusion from the Figure 3 that refrigerating at different temperatures, with frozen time increasing, the salt-soluble protein content showed a downward trend. The lower frozen storage temperature, the more slowly salt-soluble protein content decreased. Under the temperature of -18°C, the change in former 45 days is great. It decreased from 47.5 mg/g to 15.2 mg/g. After 90 days, it decreased to 0; under the temperature of -25°C, the salt-soluble myofibril protein content changed rapidly from 30 days to 75 days, in the 120th days, it closes to 0; under the temperature -35°C, it changed rapidly from 120 days; under the temperature -45°C, it changed rapidly from 135 days; under the temperature -55°C and -65°C, it changed small after 6 months.

Features function of protein is determined by actomyosin salt-soluble protein. After protein denatured, the actomyosin salt-soluble protein decreased and the content of salt-soluble protein also decreased. Therefore, the content of salt-soluble protein, in a certain extent, reflected the penetration of proteins (Somjit et al., 2005).
3.3 Activity of Ca\textsuperscript{2+}ATPase Analysis

We can draw the conclusion from the Figure 4 that under the temperature of -18\textdegree C, -25\textdegree C, -35\textdegree C, -45\textdegree C, it changed obvious, however, -55\textdegree C and -65\textdegree C it changed small. Ca\textsuperscript{2+}-ATP activity declined with frozen storage time. The lower temperature, the better ATP activity maintained the higher. Activity of Ca\textsuperscript{2+}-ATPase Was directly related to the degree of actomyosin denaturation, thus, determined the Ca\textsuperscript{2+}-ATP activity had the significance in study the Protein Traits as well as judged the degree of act myosin denaturation (Hatful et al., 2012). On the one hand, Some people thought the reason of decrease the Ca\textsuperscript{2+}-ATPase’s activity was caused by the configuration change in the myosin’s globular head. On the other hand, interactions rearrangement in protein was also been thought to cause the Ca\textsuperscript{2+} ATP activity decreased (Li et al., 2009).

3.4 Water-Holding Capacity Analysis

Water is one of the most important ingredients in meat and meat products. The water of muscles is about 75\% and it has relation with the structure, tenderness, flavor, color, processing characteristics of meat products. Water holding capacity will directly affect the meat's quality and economic benefits.
We can draw the conclusion from the figure 4 that under the temperature of -18°C. WHC decreased to 35%, -25°C it decreased to 43%, -35°C it decreased to 27%, -45°C it decreased to 23%, -55°C it decreased to 17%, -65°C it decreased to 16%. WHC decreased because the hydrophobic bonding of protein was damaged. Molecule of water of affinity protein became into free water. Meanwhile the combination chance of Amino acid was increased and the degeneration of protein condensed during frozen storage (Bengkulu et al., 2003).

4. Summary

Different frozen temperatures significantly impacted on the texture and biochemical characteristics of tuna back muscle. With frozen time increasing, hardness, springiness of tuna muscle decreased, the higher frozen storage temperature, the worse texture. With frozen time increasing, the content of act myosin salt-soluble protein, and Ca^{2+} ATP activity showed a downward trend. The higher frozen temperature is, and the higher degree of protein penetration.

Change of texture related to protein denaturation, but the function features of protein is determined by actomyosin salt-soluble protein, thus change of texture related to the content decreasing of actomyosin salt-soluble protein. Under the temperatures of -55°C, the change of the content of actomyosin salt-soluble was not obvious and the change of texture was also small. Thus refrigerating in -55°C could keep the best quality of tuna during these six months.
