On a Non Logsymplectic Logarithmic Poisson Structure with Poisson Cohomology Isomorphic to the Associated Logarithmic Poisson Cohomology

Joseph Dongho

Abstract

The main purpose of this article is to show that there are non logsymplectic Poisson structures whose Poisson cohomology groups are isomorphic to corresponding logarithmic Poisson cohomology groups.

Keywords: log-symplectic structure, poisson cohomology, log-poisson cohomology, poisson structures

1. Introduction

Symplectic geometry was discovered in 1780 by Joseph Louis Lagrange when he considered the non constants variable and defined the bracket of two such elements. From symplectic manifold, Poisson defined his brackets as tool for classical dynamics. Charles Gustave Jacobi realized the importance of those bracket and elucidated their algebraic properties. Sophus Lie and others authors began the study of their geometry. Connection of poisson geometry with numbers of areas including harmonic analytic, mechanics of particles and continua; completely integrable systems, justify this recent development. It is interested to recall that number of proprieties and results in this theory was developed in the case of differential manifold. Too few authors have worked in the case of singular varieties. J. Huebschmann in (Huebschmann, J., 1990) study in 1990 Poisson algebra and apply its Lie-Rinehart cohomology in the study of their geometric quantization. A. Polishchuk in (Pichereau, A., 2006) study in 1997 the Poisson brackets in algebraic framework.

In 2002 Ryushi Goto (Goto, R., 2002), with the aim of generalizing the approach of the symplectic, Atiyah class to the construction of the invariants of knots, defined the logsymplectic manifold and study several examples. The notion of logsymplectic manifold is based on the theory of logarithmic differential forms extensively study in (Saito, K., 1980). Logsymplectic manifold is simply a complex manifold $X$ equipped with a symplectic form $\omega$ that has simple poles along a hypersurface $D \subset X$. In other words, Poisson structures defined on $X - D$ by any logsymplectic form $\omega$ extends to a Poisson bracket on all $X$ whose pfaffian in a reduced defining equation for $D$. Logsymplectic manifolds can arise when one attempts to compactify symplectic manifolds. Many modulus space in algebraic geometry and gauge theory come equipped with logsymplectic structure. Such Poisson structure can then play an important role in geometric quantization of many classical observable. According to I. Vaisman in (Vaisman, I., 1991), obstruction of quantization of such classical space is measure by Poisson cohomology. But it style very difficult to determine explicit form of Poisson cohomology as we can see in (Pichereau, A., 2006) and (Monnier, Ph., 2002).

In other to propose an alternative method in the computation of such Poisson cohomology, the first author introduce in (Dongho, J., 2012) the notion of logarithmic principal Poisson structure and prove that such Poisson structure induced a Lie-Rinehart structure on the module of logarithmic differential form along a finite generated ideal $I$, from which he introduce the notion of logarithmic Poisson cohomology, and prove that such logarithmic Poisson cohomology are in general different to the associated Poisson cohomology. It was also prove in (Dongho, J., 2012) that when logarithmic Poisson structure are logsymplectic one, the two, Poisson cohomology and logarithmic Poisson cohomology are equivalent. The main objectif of this paper is to prove that there are non logsymplectic Poisson structure with isomorphic Poisson and logarithmic Poisson cohomology.

Recently in (Dongho, J. & Yotchach, S. R., 2016), the Differential Point of view of such cohomology has been study and and apply in the prequantization of such Poisson manifold.

More general theory of logarithmic Poisson cohomology and logarithmic Poisson algebra is in preparation in (Dongho, J., et al.).
The main results of this paper are:

**Proposition 1** The Poisson cohomology groups of the Poisson algebra

\((\mathcal{A} = C[x, y], [x, y] = x^0), (n \in N^*)\) are

\[ H^0_p \cong C, \quad H^1_p \cong C, \quad H^k_p \cong 0 \quad \forall k \geq 2 \quad \text{when} \quad n = 1 \]

and for all \(n \geq 2\),

\[ H^0_p(x^0) \cong C \]
\[ H^1_p(x^0) \cong C_{n-1}[x] \oplus C[y] \oplus xC[y] \oplus \cdots \oplus x^{n-2}C[y] \]
\[ H^2_p(x^0) \cong C[y] \oplus xC[y] \oplus \cdots \oplus x^{n-2}C[y] \]
\[ H^k_p(x^0) \cong 0 \quad \forall k \geq 3 \]

and

**Proposition 2** The logarithmic Poisson cohomology groups of the Poisson structure defined by the logarithmic Poisson 2-form \(\pi = x^0 \partial x \wedge \partial y\), which is logarithmic along the ideal \(I = x^0C[x, y]\) are

\[ H^0_{ps}(x^0) = 0 \quad \text{for} \quad n \geq 3 \]
\[ H^2_{ps}(x^0) = \bigoplus_{i=0}^{n-2} x^iC[y] \]
\[ H^k_{ps}(x^0) = C_{n-1}[x] \oplus \bigoplus_{i=0}^{n-2} x^iC[y] \]

Those can be generalize to the case of any algebra with two generator over a non zero characteristic ring.

2. \(A\)-module of Differential Form

It follows that, \(A = C[x, y]\), \(\Omega_A\) is the \(A\)-module of differential form on \(A\) and \(Der_A\) the \(A\)-module on derivations of \(A\). Then, \(\Omega_A = (dx, dy)_A\) and \(Der_A = \langle \partial x, \partial y \rangle_A\).

For any \(k \in N^*\), \(Alt^k(\Omega_A, A)\) denote the \(A\)-module of \(k\)-multilinear skew symmetric form on \(\Omega_A\). By convention, \(Alt^0(\Omega_A, A) = A\) and then \(Alt^k(\Omega_A, A) \cong \wedge^k Der_A\). Then,

\[ Alt^1(\Omega_A, A) \cong Der_A \cong A \times A \]
\[ Alt^2(\Omega_A, A) \cong Der_A \wedge Der_A = \langle \partial x \wedge \partial y \rangle_A \cong A \]
\[ Alt^k(\Omega_A, A) \cong 0 \quad \text{pour tout} \quad k \geq 3 \]

We deduce the following cochain complex

\[
\begin{array}{cccc}
0 & \longrightarrow & A & \overset{d^0}{\longrightarrow} & A \times A & \overset{d^1}{\longrightarrow} & A & \overset{d^2}{\longrightarrow} & 0 \\
\end{array}
\]

where \(d^i, i = 0, 1, 2\) are associated Poisson differential and there are defined by

\[
d^0 \varphi(\alpha) = H(\alpha) \varphi \quad \text{for} \quad \varphi \in A \\
d^1 \varphi(\alpha_1, \alpha_2) = H(\alpha_1) \varphi(\alpha_2) - H(\alpha_2) \varphi(\alpha_1) - \varphi([\alpha_1, \alpha_2]) \quad \text{for} \quad \varphi \in Alt^1(\Omega_A, A), \alpha_1, \alpha_2 \in \Omega_A \\
d^2 = 0 \quad \text{for every} \quad k \geq 2
\]

\(H : \Omega_A \longrightarrow Der_A\) is the Hamiltonian map defined by \(H(da) = [a, -]\). It induce on \(\Omega_A\) a bracket \([, ,]\) defined by \([da, db] = d(\{a, b\})\). In particular, \((\Omega_A, [, ,], H)\) is a Lie-Rinehart-Poisson algebra. The cohomology groups are given by \(H^k_p = \ker d^k / \Im d^{k-1} (k \in N)\). It therefore follows that

\[ H^k_p \cong 0 \quad \forall k \geq 3 \]

For a better understanding, we address the cases \(n = 1\) and \(n = 2\) and we end with a generalization.

3. The Case \(n = 1\)

3.1 Associated Poisson Differential

Let \(\varphi \in Alt^0(\Omega_A, A) = A\), \(d^0 \varphi \in Alt^1(\Omega_A, A) \cong Der_A\) that is \(d^0 \varphi = \varphi_1 \partial x + \varphi_2 \partial y\) with \(\varphi_1, \varphi_2 \in A\). But \(d^0 \varphi(\alpha) = H(\alpha) \varphi\) for \(\alpha \in \Omega_A\). Taking successively \(\alpha = dx\) and \(dy\) we obtain \(\varphi_1 = H(dx) \varphi\) and \(\varphi_2 = H(dy) \varphi\).
On the other hand, \( H(dx) \in \text{Der}_A \) i.e; \( H(dx) = a_1 \partial x + a_2 \partial y, a_1, a_2 \in A \). So, \( H(dx)(x) = a_1 = 0 \) and \( H(dy)(x) = a_2 = \{x, y\} = x \). Therefore \( H(dx) = x \partial y \). Similarly we can show that \( H(dy) = -x \partial x \) therefore
\[
d^0 \varphi = x \frac{\partial \varphi}{\partial y} - x \frac{\partial \varphi}{\partial x} \approx (x \frac{\partial \varphi}{\partial y}, -x \frac{\partial \varphi}{\partial x})
\]
For \( \varphi = \varphi_1 \partial x + \varphi_2 \partial y \in \text{Alt}^1(\Omega_A, A), d^1 \varphi \in \text{Alt}^2(\Omega_A, A) \cong \Lambda^2 \text{Der}_A \) i.e;
\[
d^1 \varphi = \varphi_1 \partial x \wedge \partial y, \varphi \in A. \]
Or \( d^1(\varphi_1, \varphi_2) = H(\varphi_1, \varphi_2) = H(\varphi_1, \varphi_2) - \varphi_1(\varphi_2) \) for \( \varphi \in \text{Alt}^1(\Omega_A, A), \varphi_1, \varphi_2 \in \Omega_A \). In particular, for \( \alpha_1 = dx \) and \( \alpha_2 = dy \), we get \( \psi = H(dx) \phi(dy) - H(dy) \phi(dx) - \varphi([dx, dy]) = x \frac{\partial \varphi_2}{\partial y} + x \frac{\partial \varphi_1}{\partial x} - \varphi_1 \). Therefore,
\[
d^1 \varphi = (x \frac{\partial \varphi_1}{\partial x} + x \frac{\partial \varphi_2}{\partial y} - \varphi_1) \partial x \wedge \partial y
\]

3.2 Calculation of Cohomological Groups

3.2.1 Expression of \( H_p^0(\alpha) \)

By definition \( H_p^0 = \ker d^0 / \text{Im} d^{-1} \) with \( d^{-1} : 0 \rightarrow A \) i.e; \( H^0 = \ker d^0 \). Let \( \varphi \in A, d^0 \varphi = 0 \) if and only if \( x \frac{\partial \varphi}{\partial x} = x \frac{\partial \varphi}{\partial y} = 0 \) That is \( \varphi \in C \). Therefore,
\[
H_p^0 \cong C
\]

3.2.2 Expression of \( H_p^2 = \ker d^2 / \text{Im} d^1 \)

Obviously, \( \ker d^2 = A \) Let \( \varphi \in A, \) we can write
\[
\varphi = -\varphi_1 + x \frac{\partial (-\varphi_1)}{\partial x} + x \int \frac{\partial \varphi}{\partial x} dy = d^1(-\varphi, \int \frac{\partial \varphi}{\partial x} dy)
\]
d\(^1\) is an epimorphism and we have
\[
H_p^2 \cong 0
\]

3.2.3 Expression of \( H_p^1(\alpha) \)

\( (\varphi_1, \varphi_2) \in \ker d^1 \) if and only if \( \varphi_1 = x(\frac{\partial \varphi_2}{\partial y} + \frac{\partial \varphi_1}{\partial x}) \). Thus, we can write \( \varphi_1 = xu, u \in A \) therefore \( \varphi_2 = -x \int \frac{\partial u}{\partial x} dy + b(x) \) with \( b(x) \in C[x] \). It was therefore
\[
\ker d^1 = \{(xu, -x \int \frac{\partial u}{\partial x} dy) + (0, b(x)); u \in A, b(x) \in C[x]\}
\]
Let
\[
\beta : A \rightarrow \ A \times A
\]
\[
u \mapsto (xu, -x \int \frac{\partial u}{\partial x} dy)
\]
\( \beta \) is a monomorphism and we have
\[
\ker d^1 = \beta(A) \oplus (0 \times C[x]) = \beta(A) \oplus (0 \times xC[x]) \oplus (0 \times C)
\]
in other hand, \( \beta(A) \oplus (0 \times xC[x]) \subseteq d^0(A) \) and \( d^0(A) \cap (0 \times C) = 0. \) Therefore, \( \ker d^1 = \beta(A) \oplus (0 \times xC[x]) \oplus (0 \times C) \subseteq d^0(A) \oplus (0 \times C) \subseteq \ker d^1 \). We deduce that \( \ker d^1 = d^0(A) \oplus (0 \times C) \); that is
\[
H_p^1 \cong C
\]

4. The Case \( n = 2 \)

In this section, we recall and generalize the methods and results obtained in (Dongho, J., 2012). By using the reasoning above, the associated Poisson differential are:
\[
d^0 \varphi = x^2 \frac{\partial \varphi}{\partial y} \frac{\partial}{\partial x} - x^2 \frac{\partial \varphi}{\partial x} \frac{\partial}{\partial y}, \quad \varphi \in A
\]
and
\[
d^1(\varphi_1, \varphi_2) = x^2 \frac{\partial \varphi_1}{\partial x} + x^2 \frac{\partial \varphi_2}{\partial y} - 2x \varphi_1, \quad \varphi_1, \varphi_2 \in A
\]
4.1 Explicit Expression of Associated Cohomological Groups

4.1.1 Expression of $H^0_p(x^2)$ and $H^1_p(x^2)$

By direct computation, we have:

$$H^0_p \cong C$$

By definition, we have $\ker d^2 = A$ and $\text{Im} d^1 \subseteq xA$. For $\varphi \in A$, we have

$$x\varphi = -2x(\frac{1}{2}\varphi) + x^2 \partial x(-\frac{1}{2}\varphi) + x^2 \partial y\left(\int \partial x(\frac{1}{2}\varphi)dy\right) = d^1\left(-\frac{1}{2}\varphi, \int \partial x(\frac{1}{2}\varphi)dy\right).$$

That is $\text{Im} d^1 = xA$. In other hand $A = C[y] \oplus xA$. Therefore

$$H^0_p(x^2) \cong C[y]$$

4.1.2 Expression of $H^1_p(x^2)$

Let $\varphi_1, \varphi_2 \in A; (\varphi_1, \varphi_2)$ is a 1-cocycle if and only if $2\varphi_1 = x(\frac{\partial \varphi_1}{\partial x} + \frac{\partial \varphi_2}{\partial y})$. We deduce that $\varphi_1 = xu, u \in A$ and consequently $\varphi_2 = \int (1 - x\partial x)udy + b(x)$ with $b(x) \in C[x]$ i.e;

$$\ker d^1 = \{(xu, \int (1 - x\partial x)udy) + (0, b(x)), u \in A, b(x) \in C[x]\}$$

Let

$$\beta : A \rightarrow xA \times A$$

$$u \mapsto (xu, \int (1 - x\partial x)udy)$$

$\beta$ is a monomorphism and we have $\ker d^1 = \beta(A) \oplus (0 \times C[x])$. Since $A = C[y] \oplus xA$, we obtain

$$\ker d^1 = \beta(C[y]) \oplus \beta(xA) \oplus (0 \times x^2C[x]) \oplus (0 \times C_1[x])$$

where $C_1[x] = \{a_0 + a_1x; a_0, a_1 \in C\}$ is the vector space of polynomials of degree less than or equal to 1. In other hand, we have $\beta(xA) \oplus (0 \times x^2C[x]) \subseteq d^0(A)$ et $d^0(A) \cap [0 \times C_1[x]) \oplus \beta(C[y])] = 0$. Therefore

$$\ker d^1 \leq d^0(A) \oplus \beta(C[y]) \oplus (0 \times C_1[x]) \leq \ker d^1$$

i.e;

$$\ker d^1 \cong d^0(A) \oplus \beta(C[y]) \oplus (0 \times C_1[x])$$

then

$$H^1_p \cong C_1[x] \oplus C[y]$$

5. Generalization ($n \geq 2$)

At this stage, the calculation of differentials is no longer a secret. We therefore obtains

$$d^0 \varphi = \left(x' \frac{\partial \varphi}{\partial y}, -x' \frac{\partial \varphi}{\partial x}\right)$$

$$d^1(\varphi_1, \varphi_2) = x^n \frac{\partial \varphi_1}{\partial x} + x^n \frac{\partial \varphi_2}{\partial y} - nx^{n-1} \varphi_1$$

with $\varphi, \varphi_1, \varphi_2 \in A$.

5.1 Calculation of Associated Poisson Cohomological Groups

In this section, we compute all Poisson cohomological groups associated to the above Poisson complex.

5.1.1 Calculation of $H^0_p$

For any $\varphi \in A$, we have $d^0 \varphi = 0$ if and only if $\varphi = \text{cte} \in C$. We deduce that

$$H^0_p \cong C$$
5.1.2 Calculation of $H^2_p$

By definition, $\ker d^2 = A$ and $\text{Im} d^1 \subseteq x^{n-1} A$. For $u \in A$, we have

$$x^{n-1} u = -nx^{n-1} \left( -\frac{1}{n} u \right) + x^n \frac{\partial}{\partial x} \left( -\frac{1}{n} u \right) + x^n \frac{\partial}{\partial y} \left( \int \frac{\partial}{\partial x} \left( -u \right) dy \right)$$

We deduce that $\text{Im} d^1 = x^{n-1} A$. In addition,

$$A = C[y] \oplus x C[y] \oplus \cdots \oplus x^{n-2} C[y] \oplus x^{n-1} A.$$

Therefore

$$H^2_p \cong C[y] \oplus x C[y] \oplus \cdots \oplus x^{n-2} C[y]$$

5.1.3 Calculation of $H^1_p$

Let $(\varphi_1, \varphi_2) \in A^2$, $d^1(\varphi_1, \varphi_2) = 0$ if and only if $n \varphi_1 = x \frac{\partial \varphi_1}{\partial x} + \frac{\partial \varphi_2}{\partial y}$. Thus $\varphi_1 = xu$ with $u \in A$ and consequently $\varphi_2 = \int (n - 1 - x \frac{\partial}{\partial x})udy + b(x)$ with $b(x) \in C[x]$. Therefore,

$$\ker d^1 = \{(xu, \int (n - 1 - x \frac{\partial}{\partial x})udy) + (0, b(x)), u \in A, b(x) \in C[x]\}$$

Consider the application

$$\beta : A \rightarrow xA \times A$$

$$u \mapsto (xu, \int (n - 1 - x \frac{\partial}{\partial x})udy)$$

$\beta$ is a monomorphism and we have $\ker d^1 = \beta(A) \oplus (0 \times C[x])$. On the other hand, $A = C[y] \oplus x C[y] \oplus \cdots \oplus x^{n-2} C[y] \oplus x^{n-1} A$. Therefore

$$\ker d^1 = \beta(C[y]) \oplus \beta(x C[y]) \oplus \cdots \oplus \beta(x^{n-2} C[y]) \oplus \beta(x^{n-1} A) \oplus (0 \times x^n C[x]) \oplus (0 \times C_{n-1}[x])$$

with $C_{n-1}[x] = \{a_0 + a_1 x + a_2 x^2 + \cdots + a_{n-1} x^{n-1} ; a_0, \cdots, a_{n-1} \in C\}$ denoting the vector space of polynomials of degree less than $n - 1$. Let us show now that $\beta(x^{n-1} A) \oplus (0 \times x^n C[x]) \subseteq d^0(A)$. Let $u \in A$ and $b(x) \in C[x]$,

$$\beta(x^{n-1} u + (0, x^b(x))) = \left( x^n u, \int (n - 1 - x \frac{\partial}{\partial x})u dy + x^n b(x) \right)$$

$$= \left( x^n u, -x^n \int \frac{\partial u}{\partial x} dy + x^n b(x) \right)$$

$$= \left( x^n u, -x^n \frac{\partial}{\partial x} \left[ \int \frac{\partial u}{\partial x} dy - \int b(x) dx \right] \right)$$

$$= \left( x^n \frac{\partial}{\partial x} \left[ \int u dy - \int b(x) dx \right], -x^n \frac{\partial}{\partial x} \left[ \int u dy - \int b(x) dx \right] \right)$$

$$= d^0 \left( \int u dy - \int b(x) dx \right)$$

By a simple computation, we have

$$d^0(A) \cap \left( \beta(C[y]) \oplus \beta(x C[y]) \oplus \cdots \oplus \beta(x^{n-2} C[y]) \oplus (0 \times C_{n-1}[x]) \right) = 0$$

Furthermore, $\beta(C[y]), \beta(x C[y]), \cdots, \beta(x^{n-2} C[y]), (0 \times C_{n-1}[x])$, $d^0(A)$ are parts of $\ker d^1$. We deduce that

$$\ker d^1 \subseteq d^0(A) \oplus \beta(C[y]) \oplus \beta(x C[y]) \oplus \cdots \oplus \beta(x^{n-2} C[y]) \oplus (0 \times C_{n-1}[x]) \subseteq \ker d^1$$

and then,

$$\ker d^1 = d^0(A) \oplus \beta(C[y]) \oplus \beta(x C[y]) \oplus \cdots \oplus \beta(x^{n-2} C[y]) \oplus (0 \times C_{n-1}[x])$$

since $\beta$ is a monomorphism, we have

$$H^1_p \cong C_{n-1}[x] \oplus C[y] \oplus x C[y] \oplus \cdots \oplus x^{n-2} C[y]$$
Proposition 3 The Poisson cohomology groups of the Poisson algebra \((\mathcal{R} = C[x,y], [x,y] = x^0)\), \((n \in N^*)\) are

\[
H^0_p \cong C, \quad H^1_p \cong C, \quad H^k_p \equiv 0 \quad \forall k \geq 2 \quad \text{when} \quad n = 1
\]

and for all \(n \geq 2\),

\[
H^0_p \equiv C, \\
H^1_p \equiv C_{n-1}[x] \oplus C[y] \oplus xC[y] \oplus \ldots \oplus x^{n-2}C[y] \\
H^2_p \equiv C[y] \oplus xC[y] \oplus \ldots \oplus x^{n-2}C[y] \\
H^k_p \equiv 0 \quad \forall k \geq 3
\]

6. Associated Logarithmic Poisson Cohomology

The Poisson 2-form remain \(\pi = x^0 \partial_x \wedge \partial_y\) and the module of 1-form logarithmic along \(x^0A\) is \(\Omega_{\mathcal{R}}(LogI) = \frac{dx}{x}C[x,y] \oplus C[x,y]dy\) and the associated logarithmic Hamiltonian map is \(H = \frac{dx}{x}\). This Hamiltonian map induced the following complex

\[
0 \rightarrow A \xrightarrow{\partial_y} A \otimes A \xrightarrow{\partial_x} A \rightarrow 0
\]

where \(\partial_y f = x^{n-1}(\partial_y f, -x\partial_x f)\) and \(\partial_x f_1, f_2 = x^{n-1}(\partial_y f_2 + x\partial_x f_1, -(n-1)f_1)\). It follow that The order zero logarithmic Poisson cohomology group is \(H^0_{PS} = C\). In order to determine \(H^1_{PS}\) and \(H^2_{PS}\), \(A\) is decomposed as follows: \(A = C[y] \oplus xC[y] \oplus \ldots \oplus x^{n-2} \oplus x^{n-1}C[x,y]\). So; for all \(g_0(y) + xg_1(y) + \ldots + x^{n-2}g(y) + x^{n-1}g_{n-1}(x,y) = g(x,y) \in A\), we have \(g \in \Omega^1(A)\) if and only if \(g_{n-1}(y) = \partial_y f_2 + x\partial_x f_1 - f_1\) and \(g_i = 0\) for all \(i \in \{0, \ldots, n-2, n\}\); for some \(f_1, f_2 \in A\). Therefore, given \(f_1 \in A\), there exist \((a(x) \in C[x]\) such that \(f_2 = \int g_{n-1} + (n-1)f_1 - x\partial_x f_1)dy + a(x)\). In particular, for \(f_1 = g_{n-1}\) and \(a(x) = 0\), we have \(f_2 = \int (ng_{n-1} - x\partial_x g_{n-1})dy\).

Moreover, for all \(n \neq g_0(y) + xg_1(y) + \ldots + x^{n-2}g(y)\), the following equation

\[
x^{n-1}(\partial_y f_2 + x\partial_x f_1, -(n-1)f_1) = g_0(y) + xg_1(y) + \ldots + x^{n-2}g(y).
\]

haven’t solution in \(A \otimes A\). This implies \(A = \Omega^1(A \otimes A) \oplus \bigoplus_{i=0}^{n-2} x^iC[y]\). Therefore

\[
H^2_{PS} = \bigoplus_{i=0}^{n-2} x^iC[y]
\]

Let \((f_1, f_2) \in A \otimes A\). It is an element of \(Ker(\partial_y)\) if and only if \(\partial_y f_2 = (n-1)f_1 - x\partial_x f_1\). That is \(f_2 = \int ((n-1)f_1 - x\partial_x f_1)dy + b(x)\). We define the following map \(A \xrightarrow{\eta} A \otimes A\) by \(\eta(u) = (u, \int ((n-1)u - x\partial_x u)dy)\). It is a monomorphism of \(C\)-modules and it follows from the above description of \(Ker(\partial_y)\) that

\[
Ker(\partial_y) = \eta(A) \oplus C[x]
\]

In addition, for all \(g \in \eta(x^{n-1}C[x,y]) \oplus (O_A \times x^0C[x])\), there exist \(u \in C[x,y] \) and \(v \in C[x]\) such that \(g = \eta(x^{n-1}u) + (0, x^n v(x)) = x^{n-1}(u, -x(\int \partial_x dy - v))\). This element is in \(\partial_y(A)\) if and only if, there exist \(a \in A\) such that \(\partial_y(a) = g\). This imply that there exist \(c(x) \in C[x]\) such that \(a = \int udv + c(x)\) and \(\partial_x(a) = \partial_x dy - v(x)\). But this imply that \(c(x) = - \int v(x)dx\) and then \(a = \int udv - \int v(x)dx + \eta(x^{n-1}C[x,y] \oplus (O_A \times x^0C[x])) \subset \partial_y(A)\). In other hand the following equation in \(u\) have no solution in \(C[x,y]\)

\[
\left\{
\begin{align*}
  x^n \partial_y du & = \sum_{i=0}^{n-2} x^i g_i(y) \\
  x^n \partial_x u & = \sum_{i=0}^{n-2} x^i \int g_i(y)dy + \sum_{i=0}^{n-1} a_i x^i
\end{align*}
\right.
\]

Therefore \(Ker(\partial_y) \cong C_{n-1}[x] \oplus \eta(\bigoplus_{i=0}^{n-2} x^iC[y])\) and then

\[
H^1_{PS}(x^n) \cong C_{n-1}[x] \oplus \eta(\bigoplus_{i=0}^{n-2} x^iC[y])
\]
This complete the proof of the following proposition

**Proposition 3** The logarithmic Poisson cohomology groups of the Poisson structure defined by the logarithmic Poisson 2-form $\pi = x^n dx \wedge dy$, which is logarithmic along the ideal $I = x^6C[x, y]$ are

\[
H^n_{PS} = 0 \quad \text{for} \quad n \geq 0
\]

\[
H^2_{PS} = \bigoplus_{i=0}^{n-2} x^i C[y]
\]

\[
H^1_{PS}(x^n) \cong C_{n-1}[x] \oplus \eta(\bigoplus_{i=0}^{n-2} x^i C[y])
\]
