Abstract
The article analyzes the changes in the USD, to evaluate the influence of gross domestic product in the United States the value of the United States dollar, the influence of gross domestic product of the United States on the value of the United States dollar against the euro, the models of the linear dependence of the USD against the European currency, raschetan coefficient of pair of linear correlation, characterizing the degree of dependence of the United States dollar against the euro on the dynamics of the index of real GDP in the United States of a linear model.

Keywords: modeling, exchange rate, exchange rate changes, the gross domestic product, the United States, the euro, the index, a linear function

1. Introduction
It is known that the exchange climate of the state takes important effect on the economic, investment and social processes in the society (Aleksandrovich JA, 2005). And one of the significant challenges of the exchange policy is to implement the concerted actions of different states in the interest of macroeconomic regulation and ensuring the currency markets stability (Ivanter A., Peresetsky A., 1999). Many economists try to reveal regularities of exchange rates formation, which in its turn forms the basis for decision-making to overcome the crisis developments in the economy and for financial losses minimizing (Balatsky EV, 2005; OA Gulyaev, 2008; P. Kryukov A. 2011; Panilov MA, 2009; Bogoviz AV, 2013).

However, the problem of forecasting and modeling of exchange rates also is a complex multifactorial problem to which the focused attention of scientists and specialists is paid. Thus, in the P.A. Kryukov's work "The methodology of the exchange rate dynamics modeling" an overview of modern empirical research of currency market analyzing and forecasting methods and description of a new methodological approach to the modeling of exchange rate dynamics from the perspective of solving the problem of the classificivation of its conditions by methods of factor scaling and logistic regression is provided (Kryukov, P.A., 2011). The study of E. Balatsky "The exchange rates formation factors: pluralism of patterns, theories and conceptions", which presents an analysis of the analytical material accumulated in this area, is also interesting (Balatsky E., 2010).

The urgency of the chosen theme of the scientific article is conditioned, firstly, by the manifestation of the violent fluctuations in the US dollar against major world currencies, especially agains the backdrop of the negative effects of the global financial and economic crisis; secondly, by the lack of a mechanism for determining the degree of influence of the US gross domestic product dynamics on the US dollar value against major world currencies; thirdly, by the need to improve the practice of analysis of the factors affecting the change in the US dollar value against major world currencies (P.A. Kryukov, V. Kryukov, 2011).

2. Method. Gross Domestic Product of the United States is the main indicator, which reflects the condition of the national economy (Buglaev V.B., Liventsev N.N., 1998). It represents the market value of the goods and services produced during a certain period, including the income of foreign corporations and non-residents working in the
USA, and excluding the revenues of American citizens and companies, received abroad.
Within the period from January 1, 1999 to April 1, 2011 gross domestic product of the United States increased by 2,934.3 billion US dollars (27.9 percent).

The diagram of the US gross domestic product dynamics for the period of from January 1, 1999 to April 1, 2011 is shown in the Figure 1.

![Diagram of US GDP dynamics](image)

Figure 1. The US gross domestic product dynamics for the period of from January 1, 1999 to April 1, 2011

For the IV quarter of 1998 gross domestic product of the United States was 10,507.6 bln US dollars. For the I. quarter of 2011 the US gross domestic product was 13,441.9 bln US dollars.

The dynamics of US gross domestic product (hereinafter - GDP) during the concerned period is presented in the Table 1.

As of January 1, 1999, the exchange rate of US dollar to euro was 0.8572 euro for 1 US dollar at a value of GDP of the United States for the IV quarter 1998 of USD 10 507.6 billion.

For the IV quarter of 1999, GDP of the United States reached the value of USD 11 014.3 bln, while the rate of US dollar to euro was 0.992647 euro for 1 US dollar as of January 1, 2000.

As of January 1, 2001, the rate of US dollar to euro was 1.051138 euro for 1 US dollar at the value USA GDP for the IV quarter of 2000 of USD 11 334.5 bln.

For the IV quarter of 2001, GDP of the United States increased insignificantly and reached the value of USD 11 380.1 billion, while the rate of US dollar to euro was 1.132245 euro per 1 US dollar as of January 1, 2002.

Then, with a slight increase of GDP of the United States a decline of the rate US dollar to euro was observed. For the IV quarter of 2002 the GDP of the United States reached the value of USD 11 598.8 billion, while the rate of US dollar to euro fell to 0.955293 euros for 1 US dollar as of January 1, 2003. As of January 1, 2004, the rate of US dollar to euro fell to 0.793967 euros for 1 US dollar, while the value of GDP of the United States for the IV quarter 2003 was USD 12 042.8 billion.

For the IV quarter of 2004 the GDP of the United States reached the value of USD 12 410.3 billion, while the rate of US dollar to euro continued to fall to EUR 0.733299 per 1 US dollar as of January 1, 2005. As of January 1, 2006, the rate of US dollar to euro was strengthened to 0.829531 euros per 1 US dollar, while the GDP of the United States for the IV quarter 2005 was USD 12 748.7 billion.

For the IV quarter of 2006, the GDP of the United States reached the value of USD 13 060.7, while the rate of US dollar to euro fell to 0.766872 euros per 1 US dollar as of January 1, 2007.

As of January 1, 2008, the rate of US dollar to euro fell to the record lowest value of USD 0.679302 euros per 1 US dollar, while the GDP of the United States for the IV quarter of 2007, was USD 13 363.5 billion. For the IV quarter of 2008 GDP of the United States for the first time during the concerned period fell to USD 12 993.7
billion, while the rate of US dollar to euro was 0.709471 euro per 1 US dollar as of January 1, 2009.

As of January 1, 2010, the rate of US dollar to euro fell to 0.694541 euros per 1 US dollar, while the GDP of the United States for the IV quarter 2009 was USD 13 3019.0 billion. For the IV quarter of 2010, the GDP of the United States reached the value USD 13 380.7 billion, while the rate of US dollar to euro was 0.749625 euro per 1 US dollar as of 1 January 2011.

Dynamics of change in the GDP of USA and the rate of US dollar to euro during the period of January 1, 1999 to April 1, 2011 is presented in the Table 2.

Figure 2. The diagram of the dynamics of changes of the exchange ratios of the US dollar to Euro for the period of from January 1, 1999 to April 1, 2011

The diagram of dynamics of GDP in the United States and exchange ratios of US dollar to euro in the concerned period is presented in the Figure 3.

Figure 3. The diagram of dynamics of GDP in the United States and exchange ratios of US dollar to euro for the period of from January 1, 1999 to April 1, 2011

Let’s consider the dependence of the exchange ratios of US dollar to Euro on the index of the real GDP of the
United States. Nominal GDP (absolute) is expressed in current prices of the given year. Real GDP (as adjusted for inflation) is expressed in the prices of the previous or any other base year. To what extent the growth of GDP is determined by the growth of production, rather than by growth of prices is considered in the real GDP (Perron P., 1997).

The diagram of index dynamics of real GDP of the United States and exchange ratios of US dollar to Euro in the concerned period is presented in the Figure 4.

![Index Dynamics of Real GDP of the United States and Exchange Ratios of US Dollar to Euro](image-url)

**Figure 4.** The diagram of index dynamics of real GDP of the United States and exchange ratios of US dollar to Euro for the period of from January 1, 1999 to April 1, 2011

We noted above that the gross domestic product, GDP, is a general index of amount of added values created during a certain period by all manufacturers acting in the territory of the country. GDP is a generalizing indicator of the power of the economy (or vice versa, its weakness during recessions) (Pugel T.A., Lindert P.H, 2003). Its connection with the exchange rate is always obvious: the stronger GDP grows, the stronger domestic currency is. The higher the GDP is, the better the economic situation. It is one of the main indicators for the currency markets. Reaction on the publication of not only growth indicators of the main economies, but their corrected (specified) values can be very significant.

According to the quantitative theory, the growth of the country national income as a result of new goods sales leads to increased demand for transactions with the national currency (Kravtsov MA, Miksjuk SF, 2005).

National income is not an independent component, which can be changed on its own. What causes the change of national income has a great impact on the exchange rate (Keynes, 1999). Increase of the offers of goods and services to foreign markets made by a country leads to an increase in the national currency. The increase of national income due to additional expenses of government may not cause an increase of the national currency, especially if the additional money will be used to increase imports (Fedoseev V.V, Garmash A.N & others, 2005). Thus, much depends on what causes the change in the national income: an increase in the ability of the goods supply (currency rate increases) or an increase in domestic demand (the exchange rate falls) (Litinskii D.S., 2003).

The proposed mechanism for determination of the extent of influence of the USA GDP dynamics on the value of the rate of US dollar to Euro consists of two stages. At the first stage the model of linear dependence of the rate of US dollar to Euro on the dynamics of the GDP of the United States. At the second stage the extent of influence the the USA GDP dynamics on the value of the rate of US dollar to Euro by calculating the coefficient of pair linear correlation characterizing the closeness of dependency of the rate of US dollar to Euro on the dynamics of GDP of the United States on the model developed of the the first stage (Shelobaev S.I., 2005).

To define the mechanism for determination of the extent of the influence of the dynamics of the USA GDP on the value of the rate of US dollar to Euro, let's consider the statistical series of USA GDP and the exchange ratios of the US dollar (USD) to Euro during the analyzed period, on the basis of data obtained from the official website of Bank of Russia www.cbr.ru, as well as from the site www.quote.ru and www.prime-tass.ru.
One of the mathematical methods serving to align different statistical series is the method of least squares. It reduces to the fact that the existing dependence is modeled by some production function, the parameters of which are determined at the same time (Malihin V.I., 1999).

The main requirement of the least squares method consists in the fact that the sum of squared deviations of the calculated (theoretical) levels of the actual values of the dependent factor should be the lowest (minimum) (Johansen S., 2000; Oskorbin N.M., 1989).

We present the dependence of the US dollar rate on the dynamics of the GDP of the United States in the form of the production function in the following form:

$$Y_{ri} = f \left( G_{DPi} \right)$$

(1)

where: \(Y_{ri}\) is a calculated value of the US dollar rate;

\(G_{DPi}\) is the GDP of the United States.

After we denote the sum of squared deviations of the calculated (theoretical) levels of the actual values of the dependent indication by \(S\), let’s write the main requirement of this method in mathematical form.

$$S = \sum (f \left( G_{DPi} \right) - Y_{i})^2 \rightarrow \text{min}$$

(2)

where: \(Y_{i}\) is the actual meaning of the rate of US dollar;

Since \(G_{DPi}\) and \(Y_{i}\) are known values, then the sum of squares of the specified values of deviations depends on the parameters \(a_0, a_1\) which are determined. Therefore we can write that the \(S\) sum is a function of the known parameters:

$$S = f \left( a_0, a_1 \right)$$

(3)

At the point of extremum of the differentiable function its first derivative is equal to zero. The function (3) is differentiable. \(S\) is minimal, that is extremal. Therefore, we can take the partial derivatives sums of \(S\) under certain parameters and equate them to zero.

$$\frac{\delta S}{\delta a_0} = 0; \frac{\delta S}{\delta a_1} = 0$$

(4)

As a result the two equations with two determinate parameters will be obtained. The range of equations (4) constitutes the system of so-called normal equations. While solving the system of normal equations unknown parameters of the production function are found. Systems of these equations are solved by any known method (method of substitution, addition, by G. Cramer’s method (Muraviev D.G., 2006), etc.). Available parameters are recorded in the the sought-for function production function (Grishin A.F., Kotov-Darty S.F., Yagunov V.N., 2005).

Since the increase of the GDP in the United States causes the growth of the the national currency rate (unless other rate forming factors counteract more) when determining the dependence of the exchange ratios of the US dollar to the European currency, we use a linear model of dependence of the rate of US dollar on the size of the GDP of the United States.

Linear function, which models the variation of the currency rate (\(Y_{i}\)), depending on the dynamics of GDP GBP\(i\), has the form:

$$Y_{i} = a_0 + a_1 \cdot G_{BPi}$$

(5)

Then the main requirement of the least squares method, according to which the sum of the squares of deviations between the calculated and actual levels shall be minimal (Bendat J., Peirson A., 1989), can be presented in the following form:

$$S = \sum \left( a_0 + a_1 \cdot G_{BPi} - Y_{i} \right)^2 \rightarrow \text{min}$$

(6)

In equation (5) two parameters shall be determined: \(a_0\) и \(a_1\). Therefore, the partial derivatives of the \(S\) sum are written (6), under the parameters \(a_0\) and \(a_1\) and they are equated to zero.

$$\frac{\delta S}{\delta a_0} = 2 \sum \left( a_0 + a_1 \cdot G_{BPi} - Y_{i} \right) = 0$$
\[
\delta s = 2 \sum (a0 + a1 \times GBP_i - Y_i) \times 1 = 0
\]  
(7)

after trimming the both equation by 2, opening the brackets and making a term-by-term summation, we will obtain:

\[
\sum a0 + \sum a1 \times GBPi - \sum Yi = 0,
\]

\[
\sum a0 \times GBPi + \sum a1 \times GBPi^2 - \sum Yi \times GBPi = 0
\]  
(8)

Since Yi and GBPi are known amounts, the \( \Sigma Y_i \) and \( \Sigma GBP_i \) are transferred to the right side of the equations. Since \( a0 \) and \( a1 \) are the parameters, which are in this case constant numbers, they are taken beyond the summation sign.

Therefore:

\[
\sum a0 = n \times a0, \text{ where } n \text{ is the number of observations;}
\]

\[
\sum a0 \times GBPi = a0 \times \sum GBP_i;
\]

\[
\sum a1 \times GBPi^2 = a1 \times \sum GBP_i^2.
\]

Ultimately, the system of normal equations takes the form of:

\[
n \times a0 + a1 \times \sum GBP_i = \sum Yi
\]

\[
a0 \times \sum GBP_i + a1 \times \sum GBP_i^2 = \sum Yi \times GBP_i
\]  
(9)

Let’s solve this system by the determinations (by Kramer’s method). The determinant of the system (9) has the following form:

\[
\Delta = \begin{vmatrix}
\sum Y_i & \sum GBP_i \\
\sum GBP_i & \sum GBP_i^2
\end{vmatrix} = n \times \sum GBP_i^2 - (\sum GBP_i)^2
\]  
(10)

The determinants for evaluation of \( a0 \) and \( a1 \) are:

\[
\Delta a0 = \begin{vmatrix}
\sum Y_i & \sum GBP_i \\
\sum GBP_i & \sum GBP_i \times GBP_i^2
\end{vmatrix} = \sum GBP_i^2 \times \sum Y_i - \sum GBP_i \times \sum Y_i \times GBP_i
\]

\[
\Delta a1 = \begin{vmatrix}
\sum Y_i & \sum GBP_i \\
\sum GBP_i & \sum Y_i \times GBP_i
\end{vmatrix} = n \times \sum Y_i \times GBP_i - \sum GBP_i \times \sum Y_i
\]  
(11)

As a result the required parameters will be:

\[
a0 = \frac{\Delta a0}{\Delta} = \frac{\sum GBP_i^2 \times \sum Y_i - \sum GBP_i \times \sum Y_i \times GBP_i}{n \times \sum GBP_i^2 - (\sum GBP_i)^2}
\]

\[
a1 = \frac{\Delta a1}{\Delta} = \frac{n \times \sum Y_i \times GBP_i - \sum GBP_i \times \sum Y_i}{n \times \sum GBP_i^2 - (\sum GBP_i)^2}
\]  
(12)

3. Results

As a result we will obtain:
The function, modeling dependence of the value of the rate of US Dollar to Euro \((Y_i)_{\text{Euro}}\) on dynamics of GDP of the United states has the following form:

\[
Y_i^{\text{Euro}} = a_0 + a_1 \times GDP_i = 0.7146 + 1.1816E - 0.5 \times GDP_i
\]  

(13)

As a result we will obtain:

\[
a_0 = \frac{\sum GBP^2 \sum Y_i - \sum GBP \sum Y_i \times GBP}{\Delta} = \frac{7550028534.30 \times 42,8487 - 602288,4 \times 519632,3027}{50 \times 7550028534.3 \times (602288,4)^2} = 0.7146
\]

\[
a_1 = \frac{n \sum Y_i \times GBP_i - \sum GBP_i \sum Y_i}{\Delta} = \frac{50 \times 519632,302705 - 602288,4 \times 42,8487}{50 \times 7550028534.3 \times (602288,4)^2} = 1.1816E-05
\]

The function, modeling dependence of the value of the rate of US Dollar to Euro \((Y_i)_{\text{Euro}}\) on dynamics of index of the rial GDP of the United states has the following form:

\[
Y_i^{\text{Euro}} = a_0 + a_1 \times GBP_i = 0.4219 + 0.0043 \times GDP_i
\]  

(14)

The simplest system of correlation relationship is a linear relationship between two signs the pair linear correlation. Its practical importance consists in the fact that there is a system in which among the factors influencing the resultant sign one important factor stands out which basically determines the variation of resultant sign (Hamilton J.D., 1994). To determine the dependence of the rate of US dollar to the main world currencies on the dynamics of the USA GDP we will calculate the coefficient of the pair linear correlation with the following formula:

\[
cor = \frac{n \sum Y_i \times GBP_i - \sum GBP_i \sum Y_i}{\sqrt{(n \sum GBP^2 - (\sum GBP)^2) \times (n \sum Y^2 - (\sum Y)^2)}}
\]  

(15)

Linear correlation coefficient is within the range from of from 0 to 1. When the cor = 0, any dependence of \((Y_i)\) of the indicator on the factor sign \((GBP_i)\) \((i = 1,2, \ldots n)\) is absent. When \(K = 1\), there is a functional dependence. When \(0.3 \leq cor \leq 0.7\) - the relationship is average. When the linear correlation coefficient is less than 0.3 the closeness of the relationship is considered weak, when Cor is > 0.7 – it is strong (Gulyaeva O.A., 2008).
By using the data given in the table 3, let’s calculate the coefficient of pair linear correlation of dependence of the rate of the US dollar to Euro ($Y_i$) on the dynamics of GDP $Eur$ (GBP$i$):

$$
cor = \frac{n \sum Y_i \cdot \sum GBP_i - (\sum Y_i \cdot \sum GBP_i)^2}{\sqrt{(n \sum GBP_i^2 - (\sum GBP_i)^2) \cdot (n \sum Y_i^2 - (\sum Y_i)^2)}}
$$

$$
= \frac{50 \cdot 519632,3027 - 602288,4 \cdot 42,8487}{\sqrt{(50 \cdot 7550028534,3 - 602288,4^2) \cdot (50 \cdot 37,85 - 42,8487^2)}} = 0,1911
$$

The coefficient of pair linear correlation $cor < 0.3$ ($cor = 0,1911$).

By using the data given in the table 4, let’s calculate the pair linear correlation coefficient of dependence of the value of the US dollar to Euro rate ($Y_i$) on the dynamics of index of real GDP $Eur$ (GBP$i$):

$$
cor = \frac{n \sum Y_i \cdot \sum GBP_i - (\sum Y_i \cdot \sum GBP_i)^2}{\sqrt{(n \sum GBP_i^2 - (\sum GBP_i)^2) \cdot (n \sum Y_i^2 - (\sum Y_i)^2)}}
$$

$$
= \frac{50 \cdot 4390,3718 - 5012,5 \cdot 42,8487}{\sqrt{(50 \cdot 524343,67 - 5012,5^2) \cdot (50 \cdot 37,85 - 42,8487^2)}} = 0,6041
$$

The coefficient of pair linear correlation $0.3 < cor < 0.7$ ($cor = 0,6041$).

4. **Discussion**

It is important to say that scientists and specialists actively discuss the problems of modeling of currency rates on the basis of the complexity of modern macroeconomic situations (Panilov M.A., 2008; Gulyaeva O.A., 2008). The presented approaches deserve attention because they enable to use the developed models not only taking into account the particular domestic economic situation, but also in the condition of the global financial and economic crisis. Moreover, they can form the basis of predicting the dynamics of currency exchange rates, exports, imports, and the inflow/outflow of the capital.

5. **Conclusion**

Thus, the present study analyzed the influence of the dynamics of the GDP of the United States and the index of real GDP of the United States of the value of the US dollar to the euro rate, developed the mechanism of determination of extent of influence of USA GDP on the value of the US dollar to Euro rate during the period of from January 1, 1999 to April 1, 2011.

The mechanism of determination of the extent of influence of the dynamics of the USA GDP on the value of the rate of US dollar to European currency was developed.

On the basis of the number values of the currency exchange rate of the US dollar to Euro, as well as the number values of the dynamics of the USA GDP and an index of real USA GDP, the coefficients of equation of dependence of the US dollar rate on the value of the USA GDP and the index of real GDP of the United States were calculated, the linear function that models the dependence of the value of the dollar US to the Euro rate was developed.

The article the extent of influence of the dynamics of the USA GDP and an index of real USA GDP on the value of the US dollar to Euro rate was determined, as well as the parameters of linear functions, modeling the dependence of the US dollar to Euro rate on the dynamics of the USA GDP and an index of real USA GDP were calculated.

This made it possible to develop the model of the linear dependence of the value of US dollar to Euro rate on the dynamics of the USA GDP and an index of real USA GDP and to calculate the coefficient of pair linear correlation characterizing the closeness of their dependence.

However, it should be noted that further improvement of the tools of forecasting and analytical assessments of the dynamics of currency exchange rates in order to develop regulatory measures of currency policy (Shvajko P.,
providing reduction of macroeconomic instability at the national and supranational levels is of significant practical importance. To solve these problems it is necessary to continue the development and substantiation of mathematical economic models that take into account the widest possible range of macroeconomic aggregates and make it possible to quantify the dynamics of equilibrium currency exchange rates of the main world currencies depending on changes in fundamental factors. In addition, it is necessary to provide such modeling of the rate dollar to other national currencies as well.
